URBAN MICROCLIMATES

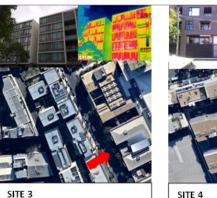

COMPARATIVE STUDY OF MAJOR CONTRIBUTORS TO THE UHI EFFECT IN SYDNEY, ADELAIDE AND MELBOURNE

Research Questions

- How can BUILDING FACADES be designed to mitigate URBAN HEAT and improve OUTDOOR THERMAL COMFORT?
- What KNOWLEDGE will assist built environment professionals to design cooler facades and more comfortable, healthier outdoor spaces?

Figure 1: Case-study sites in metropolitan Sydney

34 Rothschild Ave. Rosebery

356 George St, Waterloo

MethodologyIn-situ meter

- In-situ meteorological data collection
- Terrestrial thermal and multispectral remote sensing
- Facade modelling and image processing
- Outdoor thermal comfort assessment
- Analysis on a Geographic Information System (GIS) platform.

Figure 2: Methodological framework

- Map data to develop a predictive STATISTICAL MODEL
- Account for intervening variables such as aspect ratio and sky view factor using spatial data from cadastre and LiDAR databases.

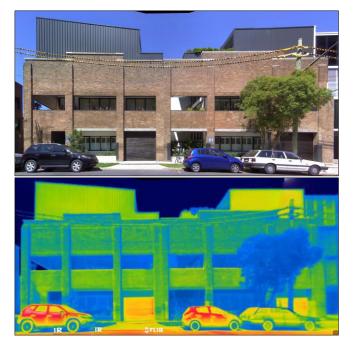

Figure 3: In-situ data collection

Figure 4: Hillshade and building footprint extraction from LiDAR data

Figure 5: Orthomosaics of building facades

Anticipated impacts

For ARCHITECTS to adopt microclimatic design principles they require diagnostic **tools** and predictive information about the microclimate effects of building design at spatial scales relevant to their decision-making.

This research advances the key challenge for CLIMATE-SENSITIVE DESIGN at all scales:

 linking physical characteristics of urban elements to intentional climate modification

The predictive model will quantify the impact of individual design decisions on outdoor climate and thermal comfort variables
